Abstract

Sodium reabsorption through the epithelial sodium channel (ENaC) at the distal segment of the kidney plays an important role in salt-sensitive hypertension. We reported previously that hydrogen peroxide (H2O2) stimulates ENaC in A6 distal nephron cells via elevation of phosphatidylinositol 3,4,5-trisphosphate (PI(3,4,5)P3) in the apical membrane. Here we report that H2S can antagonize H2O2-induced activation of ENaC in A6 cells. Our cell-attached patch-clamp data show that ENaC open probability (Po) was significantly increased by exogenous H2O2, which is consistent with our previous finding. The aberrant activation of ENaC induced by exogenous H2O2 was completely abolished by H2S (0.1 mM NaHS). Pre-treatment of A6 cells with H2S slightly decreased ENaC Po; however, in these cells H2O2 failed to elevate ENaC Po. Confocal microscopy data show that application of exogenous H2O2 to A6 cells significantly increased intracellular reactive oxygen species (ROS) level and induced accumulation of PI(3,4,5)P3 in the apical compartment of the cell membrane. These effects of exogenous H2O2 on intracellular ROS levels and on apical PI(3,4,5)P3 levels were almost completely abolished by treatment of A6 cells with H2S. In addition, H2S significantly inhibited H2O2-induced oxidative inactivation of the tumor suppressor phosphatase and tensin homolog (PTEN) which is a negative regulator of PI(3,4,5)P3. Moreover, BPV(pick), a specific inhibitor of PTEN, elevated PI(3,4,5)P3 and ENaC activity in a manner similar to that of H2O2 in A6 cells. Our data show, for the first time, that H2S prevents H2O2-induced activation of ENaC through a PTEN-PI(3,4,5)P3 dependent pathway.

Introduction

The epithelial sodium channel (ENaC) mediates Na+ absorption across epithelial cells in the kidney collecting duct, lung, distal colon, and sweat duct. Na+ transport is critical for the function of ENaC which is a negative regulator of PI3K signaling pathways [8]. Thus, loss of PTEN activity would result in the accumulation of PI(3,4,5)P3. It has been proposed that inactivation of PTEN by hydrogen peroxide (H2O2) or NAD(P)H oxidase [4]. ROS play an important role in signal transduction and have been shown to influence ENaC activity. One example is that aldosterone can regulate ENaC activity by elevating superoxide (O2-) [2] and H2O2 [3] in the kidney by stimulating NAD(P)H oxidase [4]. ROS play an important role in signal transduction and have been shown to influence ENaC activity. One example is that aldosterone can regulate ENaC activity by elevating superoxide (O2-) production in A6 cells [5].

Our recent study shows that H2O2 stimulates ENaC in A6 distal nephron cells via elevation of PI(3,4,5)P3 [6], which is known to stimulate Na+ transport [7]. PI(3,4,5)P3, the product of the phosphorylation of phosphatidylinositol 4,5-bisphosphate (PI(3,4,5)P2) by phosphoinositide 3-kinase (PI3K), plays an important role in transducing signals from growth factors, hormones and other extracellular activators to intracellular pathways. The tumor suppressor phosphatase and tensin homolog (PTEN), a lipid phosphatase, reduces the cellular concentration of PI(3,4,5)P3 and acts as a negative regulator of PI3K signaling pathways [8]. Thus, loss of PTEN activity would result in the accumulation of PI(3,4,5)P3. It has been proposed that inactivation of PTEN by H2O2 might be necessary to increase the abundance of PI(3,4,5)P3 and subsequent activation of Akt [9,10].

Hydrogen sulfide (H2S), as an important intracellular and intercellular gaseous messenger molecule, regulates multiple physiological and pathological processes, including vascular relaxation [11], angiogenesis [12], ischemia/reperfusion (I/R) injury of the heart [13], glucose homeostasis [14] and the function of ion channels [15]. Accumulating evidence demonstrates that H2S exerts protective effects against a number of injuries in many organisms. One of the main mechanisms responsible for H2S protection is antioxidation, not only by enhancing reduced glutathione (GSH, a major cellular antioxidant) [16], but also by directly scavenging superoxide anions [17], H2O2 [18] and peroxynitrite [19] to suppress oxidative stress. We therefore
hypothesize that H₂S may exert a protective effect against H₂O₂-induced ENaC activity in A6 cells. However, to our knowledge, the direct regulation of ENaC activity by H₂S has never been demonstrated. The A6 cell line, derived from the distal nephron of *Xenopus* kidney, is an established system for *in vitro* study of ENaC regulation. In the present study, we show that H₂S reverses H₂O₂-induced aberrant activation of ENaC by diminishing oxidized PTEN.

**Materials and Methods**

**Cell Culture**

A6 cells are an established renal cell line derived from the distal segment of *Xenopus laevis* nephron, which is an appropriate cell model for studying ENaC. A6 cells, purchased from American Type Culture Collection (Rockville, MD, USA), were grown in the medium consisting of 2 parts of DMEM/F-12 (1:1) medium (Invitrogen, USA), 1 part of H₂O₂, 15 mM NaHCO₃ (total Na⁺ = 101 mM), 2 mM L-glutamine, 10% fetal bovine serum (Invitrogen, USA), 25 units/ml penicillin, 25 units/ml streptomycin, as previously described [6]. A6 cells were cultured in plastic flasks in the presence of 1 µM aldosterone at 26°C and 4% CO₂. After the cells became 70% confluent in the plastic flasks, they were subcultured on the polyester membrane of either Transwell (Corning Costar Co, USA) for confocal microscopy assays or Snapwell (Corning Costar Co, USA) for cell-attached patch-clamp analysis. To facilitate polarization cells were cultured for at least two to three weeks before accessing experiments.

**Patch-clamp Recording**

ENaC single-channel currents were recorded using cell-attached patch-clamp configuration with an Axopatch-200B amplifier (Axon Instruments, USA) as described in our previous works [20,21]. A6 cells were thoroughly washed with NaCl solution containing 100 mM NaCl, 3.4 mM KCl, 1 mM CaCl₂, 1 mM MgCl₂, and 10 mM HEPES, adjusted to pH 7.4 with NaOH. Borosilicate glass electrodes had tip resistances of 7–10 MΩ when filled with NaCl solution. Experiments were conducted at room temperature (22–25°C). The data were acquired by application of 0 mV pipette potential and were sampled at 5 kHz and low-pass filtered at 1 kHz with Clampex 10.2 software (Molecular Devices, Sunnyvale, CA, USA). Prior to analysis, the single-channel traces were further filtered at 30 Hz. The total number of functional channels in the patch was determined by observing the number of peaks detected on the current amplitude histograms during at least 10-min recording period. The open probability (Po) of ENaC before and after application of chemicals was calculated using Clampfit 10.2 (Molecular Devices, Sunnyvale, CA, USA). Control ENaC activity was recorded at 2 min after forming the cell-attached mode when the ENaC activity had stabilized. We usually recorded at least 30 min before any experimental manipulation in the same patch.

**Stable Transfection of a6 Cells with Enhanced Green Fluorescence Protein-tagged Pleckstrin Homology Domain of Akt (EGFP-PH-Akt)**

To detect intracellular PI(3,4,5)P₃ levels, A6 cells were cultured on the polyester membrane of Transwell inserts at a high density to continuously cultured, in the presence of 600 µg/ml G418. Four weeks after transfection, cells were ready for assessing further experiments.

**Confocal Laser Scanning Microscopy**

Studies were performed using confocal microscopy (Olympus Fluoview1000, Japan) as previously described [6]. Prior to experiments, A6 cells were washed twice with NaCl solution. Immediately following each experimental manipulation, the polyester membrane that supports the A6 cell monolayer was quickly excised and mounted on a glass slide with a drop of NaCl solution to keep the cells alive. Confocal microscopy XY or XZ scanning of A6 cells was accomplished within five min. XY optical sections were performed to provide a flat view of the cells near the apical membrane, across the lateral membrane, or near the basal membrane. XZ optical sections were also performed to provide a lateral view of the cells. In each set of experiments, images were taken using the same parameter settings. The fluorescent intensity of GFP-PH-Akt represents the levels of PI(3,4,5)P₃ near the apical compartment of the cell membrane. The fluorescent intensity was measured in a randomly selected field including a group of cells by setting the amplitude of the Z-step as 9.5±0.5 µm from the basolateral membrane. Average fluorescent intensity of an individual experiment was obtained as follow: fluorescent intensity measured from a group of cells divided by the number of cells in the randomly selected field.

**Detection of Intracellular Reactive Oxygen Species (ROS)**

**by Confocal Microscopy**

A6 cells grown on polyester membrane of Transwell inserts were loaded with 2.5 µM 5-(and-6)-carboxy-2′,7′-dichlorodihydrofluorescein diacetate (carboxy-H₂DCFDA), a membrane-permeable ROS-sensitive fluorescent probe (Invitrogen, USA), which became fluorescent when oxidized. Prior to application of exogenous H₂O₂, A6 cells were treated by an iron chelator, 50 µM 2,2′-dipiridyl for three min [22]. Labeled cells were washed twice in modified DPBS before analyzed by confocal microscopy. ROS levels were represented with fluorescence intensity.

**Western Blot Analysis**

The expression of PTEN protein was examined using western blot experiments. Cells were incubated at 26°C in the medium with or without NaHS. Cells were then harvested and total protein was extracted. Cell lysate was loaded and electrophoresed on a 10% SDS-polyacrylamide gel with running buffer and transferred to polyvinylidene fluoride (PVDF) membranes. After one hr of blocking with 5% nonfat dry milk in phosphate-buffered saline (PBS), membranes were incubated with primary antibody specific to PTEN (Abcam, UK; 1:5000 dilution) or horseradish peroxidase-conjugated β-actin (Santa Cruz Biotechnology, USA; 1:5000 dilution) overnight with gentle agitation at 4°C. The next day, the membrane was incubated with a horseradish peroxidase-conjugated secondary antibody (Santa Cruz Biotechnology, USA; 1:5000 dilution) for one hr at room temperature. The membranes were developed using an enhanced chemiluminescence (ECL) kit (Invitrogen, USA) and scanned densitometry (Bio-Rad, USA). The band densities were quantified by densitometry using Quantity One Software and the image densities were normalized to densities measured in control samples.
Detection of Oxidized PTEN

Cells subjected to a various treatments including an iron chelator, 50 μM 2,2′-dipyridyl were scraped into 0.2 ml of ice-cold 50% trichloroacetic acid and transferred to microfuge tubes. The cell suspensions were sonicated briefly and then centrifuged at 2000 g for 5 min at 4°C. The supernatants were removed, and the pellets were washed with cold acetone twice and then solubilized in 0.2 ml of 100 mM Tris-HCl (pH 6.8) buffer containing 2% SDS and 40 mM n-ethylmaleimide (NEM; Sigma, USA). Portions (10 μl) of the solubilized pellets were subjected to SDS-PAGE under non-reducing conditions (without DTT) and transferred to a PVDF membrane. The membrane was then treated with PTEN specific antibody as ascribed above. Reduced and oxidized forms of PTEN were detected as described previously [10].

Chemicals and Reagents

Unless otherwise noted, all chemicals and reagents were purchased from Sigma Aldrich (St. Louis, MO. USA). H2O2 was purchased from Fisher Scientific (USA) and was diluted with NaCl solution prior to assessing experiments.

Data Analysis

Data are presented as mean ± S.E. Statistical analysis was performed with SigmaPlot and SigmaStat Software (Jandel Scientific, CA, USA). Paired t test or student t test was used for comparisons between pre- and post-treatment activities. Analysis of variance was used for multiple comparisons among various treatment groups. Differences were considered statistically when P<0.05.

Results

H2O2-induced Enhancement of ENaC Activity is Reversed by H2S in A6 Cells

To investigate the effect of H2S on H2O2-induced enhancement of ENaC activity, cell-attached patch-clamp technique was employed. Single-channel current of ENaC was recorded for about 90 min in each experiment. Since the responses had a long latency, in the figures we omitted a period of record and only showed the representative recordings for about six min before and after application of either H2O2 or NaHS (a donor of H2S) to the cells. Consistent with our previous findings, addition of 3 mM H2O2 to the basolateral bath led to a significant increase both in ENaC Po from 0.28±0.04 to 0.57±0.10 (P<0.01; n = 6) and in the single-channel amplitude of ENaC [Figure 1A] [6]. In the presence of H2O2, application of 0.1 mM NaHS to the basolateral bath led to a significant decrease in ENaC Po from 0.57±0.10 to 0.29±0.07 (P<0.01; n = 6) (Figure 1A and C). In contrast, application of 0.1 mM NaHS to the basolateral bath slightly decreased ENaC Po from 0.32±0.04 to 0.28±0.05 (P>0.05; n = 6); interestingly, H2O2 failed to increase ENaC Po in the cells pretreated with 0.1 mM NaHS 0.32±0.04 under control condition vs. 0.26±0.05 with NaHS vs. 0.24±0.07 with NaHS-H2O2; P>0.05; n = 6) (Figure 1B and D). These results suggest that H2S exerts a strong protective effect on H2O2-induced enhancement of ENaC activity in A6 cells.

H2S Attenuates Exogenous H2O2-induced Oxidative Stress in A6 Cells

Inhibition of oxidative stress is thought to account for the cardioprotective effects of H2S during ischemia/reperfusion (I/R) [13,23]. However, it is unknown whether H2S could reduce H2O2-induced oxidative stress in A6 cells. Therefore, the levels of intracellular reactive oxygen species (ROS) were examined with a fluorescent probe, DCF (refer to Materials and Methods) in the presence of H2O2, H2O2+NaHS, or NaHS, respectively. We performed experiments in the presence of an iron chelator, 50 μM 2,2′-dipyridyl, to confirm whether oxidation is due to Fenton chemistry, where we treated the cells with 2,2′-dipyridyl for three min followed by exposing to H2O2 for 30 min. Our results show that exposure of A6 cells to H2O2, in the presence of 2,2′-dipyridyl, induced significant accumulation of intracellular ROS levels (Figure 2A and 2C; the same as seen in the absence of 2,2′-dipyridyl). These results suggest that exogenous H2O2-induced oxidation is not due to Fenton chemistry. Furthermore, in the cells pretreated with 0.1 mM NaHS for 30 min, addition of 3 mM H2O2 failed to increase intracellular ROS (Figure 2B and D). We have carried out the MITT experiments to detect whether H2S affects cell viability (Text S1). The MITT assay showed that H2S at 0.05, 0.1 and 0.3 mM had no effect on cell viability (Figure S1). These results suggest that H2S can reverse H2O2-induced accumulation of intracellular ROS.

H2S Diminishes H2O2-induced Elevation of PI(3,4,5)P3 Near the Apical Compartment of A6 Cells

We have recently shown that H2O2 stimulates ENaC via elevation of PI(3,4,5)P3 near the apical compartment of the cell membrane [6]. Therefore, we reasoned that NaHS may diminish exogenous H2O2-induced enhancement of ENaC activity via reducing accumulation of PI(3,4,5)P3 near the apical compartment of A6 cells. To test this hypothesis, the cells were stably transfected with the EGFP-PH-Akt construct containing the PH domain of Akt which selectively binds to PI(3,4,5)P3. Consistent with our previous studies [24], under control conditions PI(3,4,5)P3 was detected mainly in the lateral and basal membranes (Figure 3A and D); treatment of the cells with 3 mM H2O2 for 30 min
resulted in a dramatic elevation of PI(3,4,5)P₃ near the apical compartment of cell membrane (Figure 3B and E). In contrast, when the cells were treated with 0.1 mM NaHS or co-treated with 0.1 mM NaHS and 3 mM H₂O₂ for 30 min, there was no significant accumulation of PI(3,4,5)P₃ near the apical compartment of cell membrane (Figure 3C–E). The fluorescent intensity, measured in and in the vicinity of the apical membrane, was used as a readout of PI(3,4,5)P₃ levels. The data shown in Figure 3E represent the mean value of PI(3,4,5)P₃ in or near the apical membrane of three independent experiments. These data suggest that H₂S prevents H₂O₂-induced elevation of PI(3,4,5)P₃ in or near the apical membrane of A6 cells.

**H₂S Ameliorates H₂O₂-Induced Inactivation of PTEN**

PI(3,4,5)P₃ levels are reciprocally controlled by PI3K and the lipid phosphatase PTEN. PTEN negatively regulates the PI3K signaling via dephosphorylation of PI(3,4,5)P₃ to PI(3,4,5)P₂. It has been reported that ROS can inactivate PTEN [25] and that H₂O₂ oxidizes PTEN within its catalytic domain, thus inactivating its phosphatase function [9]. Therefore, we tested whether inactivation of PTEN account for H₂O₂-induced elevation of PI(3,4,5)P₃. Although western blot data demonstrated that total PTEN expression in the cells treated with H₂O₂ for 30 min was not altered (Figure 4A and B), however, the abundance of reduced PTEN (active PTEN) was dramatically decreased in the cells respectively treated with 0.3 mM, 1 mM, and 3 mM H₂O₂ (Figure 4C and 4D). Oxidized PTEN (inactive PTEN) has two less cysteine residues available for alkylation, which results in a lower molecular weight form of the protein. Our results indicated that the abundance of oxidized (inactivated) PTEN in H₂O₂-treated cells was significantly greater, compared to that in the cells co-treated with both NaHS and H₂O₂ (Figure 4E and F). Oxidized PTEN was not detected in either control cells or in the cells pretreated with NaHS alone (Figure 4C, E and F). These results suggest that H₂S almost completely reverses H₂O₂-induced inactivation of PTEN, which accounts, at least in part, for the inhibitory effect of H₂S on accumulation of PI(3,4,5)P₃ in the apical membrane of A6 cells.

**H₂S Prevents H₂O₂-Induced Oxidative Stress in A6 Cells**

All experiments were assessed in the presence of 50 μM 2,2′-dipyridyl. The images represent the level of intracellular ROS detected by the membrane-permeable fluorescent probe, carboxy-H₂DCFDA, under indicated conditions in A6 cells. (A) The left image shows that there was a certain residual level of intracellular ROS under control condition; middle image shows a significant elevation of intracellular ROS level upon application of 3 mM H₂O₂; right image shows that this H₂O₂-induced increase in intracellular ROS was abolished by additional 0.1 mM NaHS. (B) The images represent that the intracellular ROS levels under control (left), treatment of A6 cells with 0.1 mM NaHS for 30 min (middle) followed by additional 0.1 mM H₂O₂ for 30 min (right). (C) and (D) Summarized fluorescent intensity of (A) and (B), respectively. Data were from three independent paired experiments. **P<0.01 compared with control group, ***P<0.01 compared with H₂O₂ treatment group.

doi:10.1371/journal.pone.0064304.g002
Inhibition of PTEN Leads to Accumulation of PI(3,4,5)P3 Near the Apical Compartment of Membrane

To further confirm activation of PTEN accounts for the cellular distribution of PI(3,4,5)P3, 30 nM BPV(pic) (dipotassium bisperoxo(pyridine-2-carboxyl)oxovanadate; ENZO, USA), a specific PTEN inhibitor, was used to treat A6 cells since it has an IC50 of 20–40 nM [26]. Under control conditions PI(3,4,5)P3 was mainly located at the basal and lateral membrane (Figure 3A and 5A). In contrast, the PI(3,4,5)P3 levels near the apical compartment of the cell membrane were significantly increased in A6 cells exposed to BPV(pic), to the same degree as seen in 3 mM H2O2 treated cells (Figure 5B, C and E). Compared to the cells treated with BPV(pic) alone, treatment of the cells with both BPV(pic) and H2O2 induced a slightly, but significantly additive effect on PI(3,4,5)P3 levels, probably due to additional activation of PI3K by H2O2 (Figure 5B–E). These results confirm that PTEN activity accounts for accumulation of PI(3,4,5)P3 near the apical compartment in A6 cells.

Inhibition of PTEN Enhances ENaC Po

In the following experiments we tested whether application of BPV(pic) to A6 can alter ENaC Po. As shown in Figure 6, ENaC Po was significantly increased from 0.29 ± 0.02 to 0.56 ± 0.04 by application of BPV(pic) to the apical bath (P<0.01; n = 6). In parallel with the effects on PI(3,4,5)P3 levels, treatment of the cells with both BPV(pic) and 3 mM H2O2 further increased ENaC Po from 0.56 ± 0.04 to 0.70 ± 0.04 (Figure 6; P<0.05; n = 6). Since H2O2 elevates PI(3,4,5)P3 both by activating PI3K and by inactivating PTEN, we argue that this synergistic effect of BPV(pic) and H2O2...

doi:10.1371/journal.pone.0064304.g003
on ENaC activity is probably due to H$_2$O$_2$-induced activation of PI3K [6].

**Discussion**

It is well documented that oxidative stress is one of the main causes of salt-induced kidney injury which might be an important mechanism of salt-sensitive hypertension [3,4]. Recently, we have shown that H$_2$O$_2$ stimulates ENaC [6], which plays a key role in maintaining Na$^+$ homeostasis and consequently controls systemic blood pressure. H$_2$S, an endogenous gaseous mediator, exerts various physiological and physiopathological effects *in vivo*, including anti-oxidative stress and anti-inflammatory response in heart, liver, kidney and other organs [27,28,29]. In this study, we show that H$_2$O$_2$ increases ENaC activity by elevating PI(3,4,5)P$_3$ near the apical compartment of A6 cells via both activation of PI3K and inactivation of PTEN. Moreover, our data suggest that as an antioxidant, H$_2$S attenuates H$_2$O$_2$-induced aberrant activation of ENaC in distal nephron cells by reducing PTEN oxidation.

Our previous study showed that high exogenous concentration of H$_2$O$_2$ is required to counteract the high expression level of catalase in A6 cells, in order to elevate intracellular H$_2$O$_2$, and to regulate ENaC [6]. We found that exogenous H$_2$O$_2$ does not significantly elevate intracellular ROS until the concentration of exogenous H$_2$O$_2$ was in the millimolar range. However, H$_2$O$_2$, even at 10 mM, did not result in either cell lysis or apoptosis in A6 cells [6], suggesting that the concentrations of H$_2$O$_2$ used for the current study (3 mM) should not result in any nonspecific effects due to cellular damage. Therefore, such high concentrations of H$_2$O$_2$ can be used as a tool to manipulate the levels of intracellular H$_2$O$_2$ in A6 cells and to investigate the mechanisms by which ROS stimulates ENaC. Furthermore, 0.1–0.3 mM H$_2$O$_2$ induced a similar result in mpkCCD14 cells (a mouse cortical collecting duct cell line) as seen in A6 cells (unpublished observations), with much shorter latency. Moreover, treatment of A6 cells with 0.3 mM H$_2$O$_2$ for six hrs significantly increased ENaC activity (data not shown). These results are consistent with the notion that there is a high catalase activity in A6 cells.

The H$_2$S level can be up to 0.1 mM in human blood [30] and is about 1.6 nmol/mg in intact kidney of rats [31]. Different concentrations of H$_2$S (NaHS) (0.2 mM, 0.4 mM, 0.8 mM or even higher concentration) have been used in the previous *in vitro* studies [32,33]. A recent study showed that NaHS treatment can protect human umbilical vein endothelial cells and fibroblasts against ischemia-reperfusion (I/R)-induced apoptosis [30]. In the present study, we selected the concentrations of 0.1 mM which is more proximate to its physiological levels in human blood. More importantly, our data show that hydrogen sulfide at concentration up to 0.3 mM had no effect on cell viability.

We should note that the inhibitory effect of H$_2$S on ENaC activity exhibited a long latency (~20 min). This slow effect of NaHS is consistent with what has been reported previously [34].

![Figure 4](https://example.com/fig4.png)

Figure 4. H$_2$O$_2$ oxidizes PTEN and H$_2$S protects PTEN to be oxidized by H$_2$O$_2$. All experiments were assessed in the presence of 50 µM 2,2'-dipyridyl. (A) and (B) Western blot analysis demonstrates that the total PTEN protein expression was not altered by treatment of A6 cells with 1 mM, 3 mM and 5 mM H$_2$O$_2$. (C) and (D) Western blot analysis shows that the magnitude of reduced (active) PTEN was dramatically decreased upon treatment of A6 cells with 0.3 mM, 1 mM and 3 mM H$_2$O$_2$ for 30 min; the intensity of the bands corresponding to reduced PTEN in the top panels of (C) was determined and presented as a percentage of the sum of the intensities of the bands corresponding to the oxidized and reduced proteins. (E) and (F) show that H$_2$S protected 3 mM H$_2$O$_2$ induced PTEN oxidation (n=3 in each group) **P<0.01 compared with control group; *P<0.05 compared with 0.3 mM H$_2$O$_2$ treatment group; ##P<0.01 compared with H$_2$O$_2$ treatment group.

doi:10.1371/journal.pone.0064304.g004
where the protective effect of H2S on ischemia-reperfusion induced injury, in human umbilical vein endothelial cells, required at least 20 min pretreatment of these cells with 0.1 mM NaHS. Previous studies show that H2S readily scavenges CoCl2-induced overproduction of ROS in PC12 cells [32,33]. We found that exogenous H2O2-induced accumulation of intracellular ROS in A6 cells was significantly abrogated by pretreatment of the cells with NaHS. We can not rule out the possibility that NaHS (H2S) may carry out its cytoprotective effect, at least in part, via direct chemical reaction with H2O2, albeit we did observe any visible reaction when these two chemicals were mixed at the concentrations used in current study. We speculate that one of the mechanisms underlying the protective effect of H2S on aberrant ENaC activity may be due to a direct chemical reaction of H2S with H2O2; and that this direct chemical reaction dramatically diminishes the ability of H2O2 to oxidize PTEN and subsequently enhances the apical distribution of PI(3,4,5)P3. Such direct chemical reaction has been reported by Geng et al., where H2S directly scavenges superoxide anions and H2O2, and consequently eliminates ROS-induced malondialdehyde (MDA) generation [35].

Manna and Jain reported that H2S can increase cellular level of PI(3,4,5)P3 and can enhance glucose utilization in high concentration of glucose treated adipocytes by activating PI3K and inhibiting PTEN [14,36]. These authors also demonstrated that there is a decreased cellular PI(3,4,5)P3 level and impaired glucose homeostasis in the liver of both type 1 and type 2 diabetic rats [36]. In contrast, our data suggest that NaHS did not affect total expression level of PTEN, but significantly prevented H2O2-induced inactivation of PTEN, thereby reversed H2O2-induced accumulation of PI(3,4,5)P3 near the apical compartment of A6 cells. The difference between the results obtained by Manna et al. and ours might be explained by cell model-dependence. Nevertheless, diabetes is associated with lower circulating level of H2S
H2S Prevents H2O2-Induced Activation of ENaC

Leslie and co-workers demonstrated that oxidative inactivation of PTEN by ROS/H2O2 has been reported in HEK293 cells stimulated with insulin [9], HeLa cells stimulated with epidermal growth factor [9], and fibroblasts stimulated with platelet-derived growth factor [39]. It has been shown that PI(3,4,5)P3 can laterally diffuse in the inner leaflet of epithelial cell membranes from the basolateral membrane domain, where it is generated, to the apical membrane domain [40]. Theoretically, the apical PI(3,4,5)P3 would be rapidly degraded because the lipid phosphatase PTEN is mainly located in the apical membrane in epithelial cells [24]. H2O2 not only inactivates PTEN but also activates PI3K [6] which phosphorylates PI(4,5)P2 to produce PI(3,4,5)P3. NaHS prevents H2O2 induced inactivation of PTEN, and PI(3,4,5)P3 might be due to H2O2 -induced activation of PI3K.

Oxidation of PTEN by ROS/H2O2 has been reported in A6 cells incubated with H2O2, whereas the magnitude of oxidized (inactivated) PTEN was significantly augmented in H2O2-treated A6 cells. However, there was no significant change in the abundance of total PTEN upon treatment A6 cells with H2O2. These results suggest that H2O2 inactivates PTEN by oxidizing its cysteine residues, which results in a defective catalytic inactivation. The importance of PTEN in regulating cellular distribution of PI(3,4,5)P3 is also supported by the pharmacological experiments, where application of BPV(pic), a specific PTEN inhibitor, to the cells leads to accumulation of PI(3,4,5)P3 near the apical compartment of membrane and to an increase in ENaC P0. While the cells were incubated with both BPV(pic) and H2O2, the abundance of PI(3,4,5)P3 near the apical compartment of the cell membrane and ENaC activity were increased. These synergistic effect of BPV(pic) and H2O2 on ENaC and PI(3,4,5)P3 might be due to H2O2 -induced activation of PI3K.

Consistent with our previous findings [6], H2O2 not only increases ENaC P0, but also elevates ENaC single-channel amplitude. Interestingly, the effect of H2O2 on ENaC single-channel amplitude is also abolished by NaHS. The mechanism by which H2O2 elevates ENaC single-channel amplitude remains to be determined. We also noticed that treatment of the cell with H2S alone also slightly, but insignificantly decreased ENaC P0, this result suggests that slight oxidation stress may account, at least in part, for basal ENaC activity because A6 cells we used were cultured in the presence of aldosterone, which is known to elevate ROS in A6 cells [5]. However, H2S appears to be more important for strongly activated ENaC under oxidative stress. Since oxidative stress is common in salt-sensitive kidney [3,4], further investigation of the effect of H2S on ENaC activity in animal models may benefit the clinical management of salt-sensitive hypertension.

Supporting Information

Figure S1 H2S does not affect cell viability. Cell viability was estimated by MTT assays. NaHS at concentrations of 0.05, 0.1 and 0.3 mM had no effect on cell viability.

Figure S2 Effect of 0.3 H2O2 on PI(3,4,5)P3 levels near the apical compartment of A6 cells. Left images show confocal microscopy XY sections in the vicinity of the apical, lateral, and basal membranes of A6 cells as indicated. Right images show XZ sections of A6 cells. (A) Control; (B) A6 cells were treated with 0.3 mM for one hr. (D) Summarized mean fluorescent intensities measured in and in the vicinity of the apical membrane from three independent experiments, which represent the level of PI(3,4,5)P3 near the apical compartment of the cell membrane. *P<0.05 compared with control group.

Text S1 MTT assay has been used to detect whether H2S affects viability of A6 cells.
