Session: 63. HIV Clinical Care and Outcomes
Thursday, October 5, 2017: 12:30 PM

Background. People living with HIV frequently achieve long-term viral suppression necessitating better metrics of disease burden for clinical management and research. The Veterans Aging Cohort Study (VACS) Index predicts hospitalization, mortality, and other outcomes, using routinely available clinical data. We sought to enhance the index by evaluating whether nadir CD4, CD8, CD4/CD8 ratio, white blood count (WBC) or absolute neutrophil count (ANC), albumin, and body mass index (BMI) enhanced prediction. The original index categorized predictors for ease of understanding and calculation of a risk score. We also sought to expand categories and develop a continuous variable model, suitable for use with automated calculation, to provide higher resolution.

Methods. VACS includes all HIV infected patients in VA Care. Among those who initiated ART 1996–2013, (excluding any treated for HCV infection), we obtained laboratory values from a randomly selected visit 2000–2014, at least one year after ART initiation. Patients were followed for 5-year, all cause mortality until September 30, 2016. We fit Cox models starting with currently used predictors (age, CD4, HIV-1 RNA, hemoglobin, PLT, eGFR and HCV status) and decided to include new variables based on model fit, chi-square, strength and significance of individual levels and c-statistic. Functional form for continuous variables was determined graphically. Adequacy of final models was assessed with Kaplan-Meier plots by decades of risk.

Results. Among 28,390 patients there were 7,293 deaths (7.2 per 100 person-years) in median 4.1 years of follow-up. Nadir CD4, CD8, CD4/CD8 did not improve prediction. WBC and ANC performed equally but WBC was more widely available. C-statistics improved from 0.776 for the original VACS Index (in this sample) to 0.805.

Conclusion. Addition of WBC, albumin, and BMI enhances utility of the VACS Index as a measure of overall severity of disease both as an outcome for research and for patient monitoring in the clinical setting. Validation in external cohorts is in progress.

Session: 63. HIV Clinical Care and Outcomes
Thursday, October 5, 2017: 12:30 PM

Background. In the era of effective antiretroviral therapy (ART) non-AIDS diagnoses (NAD) have emerged as significant concerns. HIV viremia is an important driver of systemic inflammation that has been linked to the development of NAD. In this study, we examined the distribution of NAD in a group of early diagnosed and treated HIV-infected individuals with equal access to care to evaluate the effect of continuous virologic suppression (CS) on NAD.

Methods. The U.S. Military HIV Natural History Study (NHS) is a prospective cohort of HIV-infected DoD beneficiaries the majority of whom are deroconverters. Medical record review and structured interviews are utilized to capture NAD. We included subjects initiating ART after 1996 if they had >2 viral loads (VLs) measured while on ART. CS was defined as having all VLs <50 copies/mL. A Cox proportional hazard model was used to evaluate the association between CS and NAD.

Results. Of the 2,642 eligible participants (93% male, 43% African-American AA), median follow-up 6.5 (IQR 3.1–12) years, 94.7% subjects (94% male, 42% AA, median follow-up 3.74 years) met criteria for CS. The median time from HIV diagnosis to ART initiation was 1.34 (IQR 0.19–5.46) years, while the median seroconversion window was 1.31 (IQR 0.8–2.1) years. A total of 402 (15.2%) NAD were recorded and were recorded (table). Factors associated with NAD included older age at ART initiation (HR 1.6 per 10-year increase [95% CI 1.4–1.8]) and female gender (HR 1.6 [95% CI 1.0–2.7]), while a higher CD4 count was protective (HR 0.93 per 50 cell increase [95% CI 0.90–0.95]). CS status was not associated with NAD (HR 0.75 [95% CI 0.50–1.11]).

Conclusion. In the ART era, about 1 in 7 NHS subjects had a NAD. The numbers of NAD in the CS subjects were lower than the rest of the cohort. While not statistically significant, the hazard ratios trended towards demonstrating a benefit for continuous virologic suppression. This trend is consistent with previous reports that have demonstrated a benefit of immunologic reconstitution and virologic control on the incidence of NAD.

561. Screening for Comorbid Conditions Among People with HIV in Medical Care
Rachael Lazar, MPH1; Laura Kersanske, MPH2; and Sarah Braunstein, PhD, MPH1; 1Bureau of HIV/AIDS Prevention and Control, New York City Department of Health and Mental Hygiene, Long Island City, New York, 2Massachusetts Department of Public Health, Boston, Massachusetts. 3Bureau of HIV/AIDS Prevention and Control, New York City Department of Health and Mental Hygiene, New York, New York

Session: 63. HIV Clinical Care and Outcomes
Thursday, October 5, 2017: 12:30 PM

Background. A significant proportion of morbidity and mortality among people living with HIV (PLWH) is attributable to non-HIV comorbid conditions. Despite the importance of detecting and treating comorbidities among PLWH, screening rates for common comorbidities are often suboptimal and may not correspond with risk factor status.

Methods. Comorbidities screening and other clinical data were obtained from the 2012 New York City (NYC) Medical Monitoring Project (MMP), a multi-site surveillance project comprised of demographically representative cohorts of PLWH receiving medical care. MMP medical record abstraction data were analyzed to
